

Topic 10.1

10.1: Comments on Reading Assignments for Module 9

Run Time Type Identification (RTTI) is another topic that causes many bitter arguments. RTTI allows you to determine, at runtime, the type of object a pointer is pointing at. Note that this is only needed for pointers in hierarchies (you should be able to convince yourself that it's not needed in any other case).

It's useful to be aware of the basic idea of RTTI. Beware of overuse, though. Perhaps the worst thing about it is that too many programmers turn to it as the first solution to a problem, when appropriate use of virtual functions often solves the same problem better and with fewer portability problems.
